Review

VR MultiPrice Analysis is a professional indicator for synthetic analysis of a currency pair. The program shows the trader a general picture of the separation for each currency included in the currency pair in question. This analysis helps determine which currency is mostly bought for other currencies, and which is mostly sold. Multi-currency analysis of a financial instrument is much better and more accurate than the analysis of a single currency pair. VR MultiPrice Analysis clearly shows which currency has buyers or sellers. The growth or fall of a currency pair can be caused by several strong factors (for example, take the EURUSD pair):

- EUR can grow only because everyone is selling USD, not only for EUR, but also for any other currency.
- EUR can grow only because everyone is buying EUR, not only for USD, but also for any other currency.
- EUR may grow after the release of important news related to the Euro zone.

VR MultiPrice Analysis shows what is really happening. Using the histogram columns, the trader can see situations when EUR is bought for other currencies, the columns will show the growth of EUR relative to other currency pairs. Also, a trader can see the growth of EUR due to the growth of the EURGBP currency pair, despite the fact that all other currency pairs are moving in different directions. Basically, the trader sees not one EURUSD currency pair, but several currency pairs at once, including the EUR and USD currencies.

Advantages

The indicator has a number of advantages, we will list only a portion of them:

- High accuracy of the indicator.
- It clearly shows the situation for the selected currency pair.
- It is possible to perform analysis on historical data using the mouse.
- The indicator automatically recalculates forward, reverse and cross rates.
- Suitable for any pair of financial instruments (Forex, Crypto).
- All the information is right in front of the trader's eyes.

- It is easy to install in the MetaTrader terminal.
- There is only small number of settings.
- The indicator is designed for MetaTrader 4 and MetaTrader 5, there are no differences between versions for different terminals.
- It is suitable for both beginners and experienced traders.
- It works on any period and any time frame.

This man is a pure mastermind. His tools surpass all expectations. In addition he gives away tools like this for free. I never met anybody at mql5 to give away tools for free which are at that level of quality. This one can be sold for hundreds of dollars easily. Thank you sooo much for your efforts, your ingenuity and your generosity Vladimir.

Great indicator.

Operation algorithm

Once installed on the chart, the indicator analyzes the currency pair by dividing it into its component currencies. For example, take the EURUSD pair. The indicator algorithm splits the pair into the first currency - EUR - and the second one - USD. In the next step, the indicator collects data for analyzing currency pairs that have EUR in them and separately collects currency pairs that contain USD. The indicator builds histograms on the selected currencies. A trader can use two vertical lines to select a period in the history to get data in the indicator columns.

Readings accuracy

It is not possible to calculate the indicator's yield since the indicator uses multiple currency pairs for readings.

Recommendations

- The most accurate and high-quality indicator is the growth of columns for the first currency and the fall of columns for the second.
- Use the indicator in conjunction with your trading strategy.
- Confirmation of your buy signal will be the growth of the first currency in multiple columns of the indicator.
- For purchases, wait for the growth of columns for the first currency, the fall of columns for the second currency does not mean that the first currency will grow.
